SELLER ENABLEMENT INTELLIGENCE · GTM AI ENABLEMENT

Phase 1 — Diagnose Before You Build

Janos Kristof · July 13, 2026

Prepared under NDA · call data anonymized

Contents

Phase 1 — Diagnose Before You Build

- Step 0 — Interrogate the brief before trusting it
- Step 1 — Mine every source, then pressure-test the one real call
  - The tell: in this call, the rep broke Sensi's own playbook
  - Who the rep is selling to (and why it's genuinely hard)
- Step 2 — What I'd go find beyond the brief
- Step 3 — The funnel: six symptoms → one root cause → one leverage point
- Step 4 — The bet (the hypothesis I'd take into Phase 2)
- Step 5 — Why this leverage point (not the others): the coverage overlap
- Scope decisions made explicit

Decision Log — How This Diagnosis Was Made

- The starting point (my first-draft instinct)
- The five course-corrections
- Corrections from the validation gate (the process caught me)
- Two decisions I made deliberately (and could defend either way)
- What I deliberately did NOT do
- The through-line

Make vs. Buy — Seller Enablement Stack

- The decision framework (applied to every component)
- The stack, component by component
- The headline answer: "Jiminny/Gong already coach — why build?"

Phase 1 — Diagnose Before You Build

GTM AI Enablement — Seller Enablement Intelligence Janos Kristof · prepared for Daniel Urcuyo & Daniel Rubin

> **How to read this.** The deliverable here is not the answer — it's the *path* to an answer I'd bet on. It walks the discovery in the order I'd run it: interrogate the brief, **mine every source we were given** (the real call, the GTM deck, the Guide Book, the product/customer materials), then lay out who I'd talk to and what data I'd pull to confirm or kill the hypothesis before building. The bet is at the end.
>
> **On the one call — an important caveat.** I treat it as a *revealing sample, not proof of a pattern*. It shows the **kind** of gaps that currently go uncaught; it does **not** establish that every rep or every call looks like this, and I make no such claim. Whether these gaps are systemic is a question the discovery plan (Step 2) answers by *sampling* — it is not an assumption baked into the diagnosis. In fact, the point is the opposite: today no one at Sensi can say how common these gaps are, because nothing measures calls at all.
>
> *Starting facts already established (from prior interviews): CRM = HubSpot; call recording = Jiminny. All references to the real sales call are anonymized (names, agency, PII removed).*

Step 0 — Interrogate the brief before trusting it

The brief hands me six neat pain points. The fastest way to build the wrong thing is to treat those six as the problem. They read as **symptoms**. My first move is to ask: *what single condition would produce all six at once?*

#	Stated pain	Symptom or root cause?
1	Fragmented tech stack, no unified system	Symptom — tooling gap
2	QA manual & mostly not happening	Symptom — no process
3	Managers overloaded, coaching gets cut	Symptom — capacity
4	Reps have no AI to get better	Symptom — tooling gap
5	Persona/product knowledge inconsistent	Symptom — content gap
6	Onboarding ramp too long	Symptom — outcome of 1–5

All six share one root: **there is no closed loop that turns each sales call into tracked, improving rep behavior.** Sensi generates a rich behavioral signal on every call and then throws it away. Nothing measures how a rep actually performed, nothing routes that into a next action, and nothing tracks whether it led to improvement. Every stated pain is a downstream consequence of that missing loop — which is why fixing any one of them in isolation (buy a KB, write a QA checklist, hire enablement) doesn't compound.

This reframing matters because it changes what "good" looks like: the win isn't a better tool, it's **installing measurement where none exists** — and measurement is also the cheapest, fastest thing one person can build.

Step 1 — Mine every source, then pressure-test the one real call

I worked all the material we were given — because the fastest way to find the *real* problem is to compare what Sensi *says* a great sale looks like (deck, Guide Book) against what the one real call *actually* shows.

Source	What I pulled from it	How it feeds the diagnosis
Situation brief	Six stated pains	Reframed as symptoms (Step 0)
Real sales call (Jiminny)	The only behavioral ground truth we have	The evidence base — teardown below
GTM deck	Sensi's *prescribed* call motion + its published proof metrics	The benchmark I measure the call against
Guide Book	Product/agent definitions; ops-pain framing	Confirms product taxonomy + buyer pain
Product / customer materials (Solo Care, customer stories, deck videos*)	Persona language, outcome claims	Rubric inputs — what a good call should cite
sensi.ai / profile	Category, ICP, business context	Grounding

*I transcribed the deck's embedded videos locally (offline, NDA-safe). They corroborate the published outcomes in customers' *own voices* — one agency owner recounts her call-to-assessment conversion climbing **33% → 85%** (plus weekly billable hours 1,189 → 2,201 and clients 88 → 220) on camera. That sharpens the point below: **credible, attributable numbers were sitting on Sensi's own customer videos — the rep ignored them and invented his own.**

Now the one real call (a ~50-minute second-stage demo/close with a home-care agency owner) — the only behavioral ground truth. **This is a single sample: I read it for the *kind* of gaps it exposes, not as evidence that all calls look like this.** Anonymized, timestamped:

Moment	What happened	Why it's a coachable signal
Open [00:37]	*"Any questions from our first conversation?"* → *"I don't have any."* then straight to screen-share	**Zero fresh discovery.** No re-confirm of goals, criteria, timeline, or decision process
Talk time (whole call)	Rep speaks ~85–90% of the call; prospect utterances are mostly "okay / right / correct"	**Severe talk/listen imbalance** — monologue, not dialogue
ROI build [32:06–35:48]	Rep repeatedly self-labels "being *very conservative*," builds to a "$623,000 back to you" number	Numbers *presented at*, not *discovered with*, the prospect
The close question [36:18]	*"Would you agree I'm being conservative?"* → *"Yes, because I have nothing to disagree."*	**Compliance, not conviction.** A leading question manufacturing false agreement — the rep doesn't catch it
Buying signal [46:54]	Prospect volunteers: *"I have been trying to sell the business for a bit."*	**The single most important fact in the call — surfaced by accident, at minute 47.** Real discovery finds this in minute 5
Signal handling [47:26–49:06]	Rep reframes ("systems and processes raise your multiple") but never qualifies: timeline? does a buyer inherit the contract? should we even proceed now?	Missed the obvious qualifying questions the signal demanded
Close [49:17–49:46]	*"We have a board meeting at the end of this month… valid until the end of the month."*	**Manufactured urgency** layered on a prospect who just said he's exiting
Next step [46:36], [49:46]	*"I'll send you an email with the five things… check in next week."*	**No firm next meeting booked** — a diffuse, low-commitment close
Product coverage	Rep correctly walked the full agent suite — Sally, Olly, the Concierge, Solo Care	**On-brand — so this is *not* a product-knowledge gap.** It isolates the defect to *discovery* and *proof*, not knowledge

What this one call demonstrates (and what I would *not* over-claim): it shows the **kind** of coachable gaps that exist and go completely uncaught, and that the raw signal to catch them lives in the transcript. It does **not** prove every call looks like this — I'd confirm the actual spread by sampling (Step 2). The load-bearing point is subtler and doesn't depend on the spread: **today nothing scores any call, so no one —**

not the rep, not the manager — knows how common these gaps are. That measurement vacuum is the problem, and it's exactly what an AI system can fill cheaply, at scale, from day one.

The tell: in this call, the rep broke Sensi's *own* playbook

What elevates this from "one rough call" to a *diagnosis worth investigating* is that the call departs from Sensi's **own** documented motion and proof standards — a mismatch a scoring loop would catch automatically and today catches never.

1. Motion inverted. Sensi's deck prescribes the agenda: *Intro → Getting to Know You & Your Business (discovery) → Product → Customer Story & Value → Q&A*. In this call the rep opened with *"I'm going to share my screen for most of this call,"* asked only *"any questions from our first conversation?"*, then ran a product tour + a self-built ROI calculator — **discovery-first became product-dump-first.**

2. Invented numbers instead of Sensi's published proof. Sensi publishes an attributable proof wall — **35% more billable hours, 2.6× inquiry→assessment conversion, 23% readmission drop, 300% retention, 80%+ hospitalization reduction**, plus the Diana story (**0%→100%** satisfaction, 14 months with no falls). The rep used **none** of it, and instead improvised:

Rep said (this call)	What Sensi actually publishes	Verdict
"$623K, unbelievably conservative"	~$500K avg savings; no total-$ ROI figure	**Invented — and it overshoots Sensi's own ceiling**
"3.3 months longer LoS, 1,000-agency survey"	"2× length of stay"; no such survey exists	**Fabricated provenance**
"Sally = 3–4× a salesperson"	"your entire inside sales force in one agent"	**Unsupported multiplier**
"90-plus / 80–83% adoption"	no adoption figure is published	**Unsupported**

Why this matters (carefully): I'm not claiming every rep does this. I'm claiming something more defensible — **Sensi already has a winning motion and a proof library, and nothing measures whether any given call uses them.** This one call shows the gap is *possible and invisible*; the fix is the loop that would make it *visible and measured*. It also hands the future rubric its two highest-value, evidence-backed dimensions: **motion adherence** (discovery before pitch) and **proof-point fidelity** (Sensi-sourced numbers, not invented ones).

Who the rep is selling to (and why it's genuinely hard)

The buyer is a **home-care agency owner/operator** (the deck's customer quotes are exactly these titles). Sensi frames their pain as **operational and financial fragility** — a *77% rise in caregiver turnover*, *89% of providers rejecting new business for lack of caregivers*, and margins that live or die on the **billable hour** and **length of stay**. That shapes the rubric: a strong Sensi call ties value to *those* levers. *(I checked deliberately: Sensi's materials do not frame the difficulty as HIPAA / Medicare / regulatory — Medicaid appears only as a prospect's question in the call. So I'm not leaning on a regulatory angle; that would be my inference, not Sensi's positioning.)*

Step 2 — What I'd go find beyond the brief

One call is a hypothesis generator, not proof. Before building, I'd run a fast, sequenced discovery. **Order matters** — I go from "what does good look like and what's been tried" (so I don't rebuild a dead end) outward to the front line, then to the data.

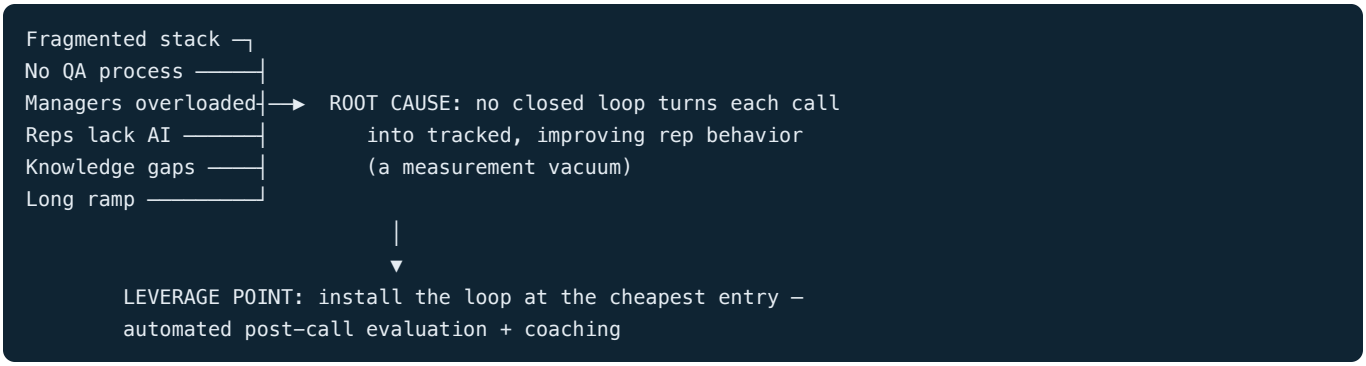

Order	Who	Why them first	Questions I'd ask
1	Daniel U. & Daniel R. (Ops leadership)	Align on the definition of "getting better" and what's already been tried	How do you know a rep is improving today? What have you tried that didn't stick, and why?
2	VP Sales / CRO	Owns the sales process the rubric must reflect	What does a great call look like by stage? Where do deals actually stall? **How many reps, teams, and calls a week — and where's the growth?** (sizes the loop)
3	3 reps: 1 top, 1 ramping, 1 struggling	Ground truth on the daily workflow; top-vs-bottom delta is the coaching target	Walk me through a recent won *and* lost call — where did each turn? How do you prep, and what do you do after? What would you *actually* use?
4	1–2 front-line managers	They're the overloaded constraint; coaching adoption lives or dies with them	What are your priorities? What are your biggest challenges? How do you coach today? *(open, not leading — let them name the constraint)*
5	RevOps / HubSpot owner	Owns the data + the integration surface	What's captured in **HubSpot** automatically vs. manually? Does Jiminny already sync to HubSpot? **What's our weekly call volume, and what % is recorded?** What activity/stage data can the loop read *and* write back?
6	Enablement / onboarding lead	Ramp is the compounding symptom	What's the ramp curriculum? What's documentation vs. shadowing vs. measured?
7	Product Marketing	Source of the persona/product-knowledge inconsistency	How do new features reach reps today? What's the lag between release and rep fluency?

External data I'd pull (and where it lives): - **Win/loss by rep and by stage** (CRM) — is the problem discovery, demo, or close? - **Ramp cohorts** — time-to-first-deal / time-to-quota by hire cohort (CRM + HR/onboarding). - **Existing call-tool analytics** (Jiminny) — are talk-ratios / trackers *already* available and simply unused? This directly changes build-vs-buy (see `make_vs_buy.md`). - **Call coverage** — how many calls/week are actually recorded? (No recordings → no loop.) - **Org sizing** — # teams · reps · calls/week and the growth trajectory (HubSpot · Jiminny · sales ops) — sizes the loop and drives the scaling/architecture questions in Phase 3. - **Stage-conversion rates** (CRM) — where in the funnel deals leak, to focus the rubric. - **New-rep onboarding survey / CSAT** — qualitative ramp friction.

How I'd turn all this into a picture — the synthesis method (not just collection): - **Sample, don't anecdote.** I would **not** assume the one call is representative. I'd score **15–20 recent calls across the three rep tiers** with an ad-hoc LLM evaluation to learn the *actual* distribution of gaps, then **review the findings with reps and sales managers** — to see how *common* each gap is and validate the rubric with the people who live it. That's how a single call becomes a diagnosis I'd bet on. - **Top-vs-bottom delta.**

Compare top performers' calls to strugglers' on the same rubric dimensions; the gap between them *is* the coaching curriculum. - **Motion-adherence + proof-fidelity coding.** Score each sampled call against Sensi's own deck agenda and proof wall (Step 1 shows both are concretely measurable). - **Triangulate quant.** Talk/listen ratio and discovery-question counts (deterministic) × win/ loss by stage × ramp cohorts → *where in the funnel* the behavior actually costs deals, so the rubric weights what matters.

Step 3 — The funnel: six symptoms → one root cause → one leverage point

Step 4 — The bet (the hypothesis I'd take into Phase 2)

> **Biggest leverage point:** an **automated post-call evaluation + coaching loop** — every call is scored against a Sensi-specific rubric, the rep gets specific feedback + a next action, the manager gets a triaged coaching queue, and every score is tracked over time.

Why I believe it: 1. **The gap is real, and today it's invisible.** This call shows the *kind* of coachable gap that exists, and the deck cross-check shows it's a departure from Sensi's *own* motion and proof standards. Whether that's one rep or many, *nothing measures it* — so the loop is what turns an unknown into a managed number (Step 1). (I'm betting on the measurement vacuum, not on a claim that all calls are weak.) 2. **It's the cheapest place to install measurement** — there is no baseline today; this *creates* the baseline from call one, which unlocks every other fix. 3. **It attacks the binding constraint** — manager capacity. Triaged, pre-analyzed calls turn coaching from an hour of review into a five-minute intervention. 4. **It compounds** — the same loop (rubric + evaluate + route + track) later templates onto onboarding, persona/product gaps, and other teams (Phase 3). The other five pains become *measurable* once the loop exists. 5. **One person can build it with AI** — which is precisely the bet this role is testing.

What I'd build to test it: a working "Rep Coach" scorecard (Phase 2) that ingests a transcript, scores it (deterministic metrics + LLM judgment with evidence quotes), and produces the rep view, the manager queue, and a trend dashboard — with the measurement layer built in.

How I'd know I'm wrong (falsification — I'd rather find this in week 2 than month 6): - Reps don't open it, or open it once and never return → the feedback isn't actionable enough. - Scores don't move behavior on flagged dimensions within ~3–4 weeks → the rubric measures the wrong things, or coaching isn't closing the loop. - Managers don't trust the scores enough to act → evidence/explainability is too thin. Each has a leading metric in the Phase 2 tool, so the hypothesis is testable, not just asserted.

Step 5 — Why this leverage point (not the others): the coverage overlap

A single-pain fix wouldn't earn the bet. This one does because **the six pains overlap**, and the artifacts the loop produces each serve several at once. Read the pains not as six separate problems but as three moves seen from different roles:

- **QA (2), manager overload (3), rep support (4)** are the *same evaluation event* viewed by three people — one scored call feeds all three. Solve one, solve three.
- **Knowledge inconsistency (5) and long ramp (6)** are the *same rubric* applied to learning — "what good looks like," measured, with targeted content to close the gap.
- **Stack fragmentation (1)** is the connective tissue the loop *is* — it threads call performance → coaching → content → outcome across Jiminny, HubSpot, Slack, and the KB.

Pain point	Proposed solution	Loop artifact that delivers it	Coverage
2 · QA not happening	Automated evaluation of every call against a consistent rubric	Rubric + per-call scorecard	● Directly solves
3 · Managers overloaded	Pre-analyzed calls, triaged coaching queue, auto-escalation on extreme gaps	Manager rollup + escalation flags	● Directly solves
4 · Reps lack AI support	Personal scorecard, top-2 focus areas, recommended micro-content before the next call	Rep view + recommendations	● Directly solves
1 · Fragmented stack	Consolidate onto **HubSpot as the single surface** (score on the call record, follow-ups as tasks, dashboards) so reps/managers stop jumping tools; the loop is the connective layer feeding it	The loop (integration spine) → **HubSpot in production**	◐ Unifies → ● in production
5 · Inconsistent knowledge	Product-claim-accuracy scoring exposes per-rep *and* systemic gaps; routes targeted content	Gap analytics + recommendations	◐ Measures & routes
6 · Long onboarding ramp	Objective ramp curve, the rubric as the onboarding standard, targeted practice	Tracked scores over time + rubric-as-standard	◐ Accelerates

`●` = the core loop solves it directly · `◐` = the loop supplies the measurement/spine, paired with a buy (KB, BI) or an integration.

The through-line: every `●` and `◐` above is powered by the *same two artifacts* — the **rubric** and the **evaluation data**. Build them once (for pains 2/3/4) and pains 1/5/6 come along for the ride. That is the definition of a leverage point: not the biggest single pain, but the **smallest build that moves the most pains** — and the same overlap is what lets it scale across teams in Phase 3 (one engine → many rubrics).

Scope decisions made explicit

- **Human reps, not the Sally AI agent.** Sensi *sells* an AI sales agent (Sally), so "seller enablement" is genuinely ambiguous. The stated pains ("our sellers are not getting better") and the one real

artifact are about **humans**. I'm targeting humans; a Sally-tuning loop is a valid future instance of the *same* pattern, noted in Phase 3.

- **HubSpot is the CRM (confirmed).** Verified through prior interviews — the production integration target is **HubSpot** (including HubSpot Workflows for routing tasks). I still **mock CRM/Slack in the prototype** (no live access, and to keep scope tight), but the production design assumes HubSpot specifically, not a generic CRM.

Decision Log — How This Diagnosis Was Made

Janos Kristof · the "how I think" companion to the deliverables

> **Why I'm showing you this.** The assignment rewards people who are "relentlessly curious about the real problem, not the stated one" and who "think in systems that compound." Those are *process* traits — invisible in a polished final answer. So this log exposes the working: where I started, where I pushed back on myself, what I deliberately cut, and why. A clean conclusion can be a lucky guess; a documented path is a repeatable skill.

The starting point (my first-draft instinct)

My initial plan was broad — I mapped all six stated pains and proposed a workstream for each: call QA, a product knowledge base, a persona knowledge base, onboarding automation, and a release-to-docs content pipeline. It was comprehensive. It was also **wrong for this assignment**, for reasons I only saw when I re-read the brief as a rubric.

The five course-corrections

1. Comprehensive → sharp. The brief says *"we expect sharpness. Pick your battles"* and asks for *one* hypothesis and *one* tool. A plan that keeps six workstreams alive fails that test on contact. I forced the funnel: six pains are **symptoms of one root cause** (no closed loop that turns calls into tracked, improving behavior). Committing to one leverage point isn't narrowing the scope — it's finding the point that makes the others move.

2. Conclusion → process. My first draft led with the answer ("build a call scorecard"). But Phase 1 is graded on the *discovery process*, not the conclusion. I rebuilt it to show the path: interrogate the brief → mine the one real artifact → sequence who I'd interview and what data I'd pull → *then* the bet. Same destination; now the map is the deliverable.

3. Stated problem → real problem. The brief's six bullets are the *stated* problem. I treated them as symptoms and went looking for the real one — starting with the single piece of behavioral ground truth we were given, the sales call. That's where the thesis got its *first* evidence: this one call shows the **kind** of coachable signal that today goes uncaptured and unscored — and nothing in the stack measures whether it happens on any other call. The call didn't prove a team-wide pattern; it revealed a **measurement vacuum** worth betting on (which I'd then size by sampling, per the diagnosis).

4. "Measurement later" → measurement is the point. The brief is blunt: *"If you can't measure it, it didn't work."* My first draft treated metrics as a reporting afterthought. I inverted it: the reason call-coaching is the leverage point is precisely that it's the cheapest place to **install measurement where there's a vacuum** — it *creates* the baseline. Measurement moved from feature to thesis.

5. Content-reuse → a pattern that compounds. My draft Phase 3 said "the product KB also feeds marketing, website, CS." That's content *reuse* — not what "systems that compound" means. I reframed it to the underlying **repeatable architecture** (the enablement loop) that re-templates to any team by swapping a rubric, and made "reusable in under a day" a literal, demonstrable test.

Corrections from the validation gate (the process caught me)

Before finalizing, I ran the deliverables through an independent validation against the assignment (coverage + completeness). It returned **REVISE** — and it was right on two things I'd have shipped otherwise:

6. I'd leaned on one source; the assignment says use them all. My first pass mined the brief + the one call and skated past the GTM deck, Guide Book, and customer materials — while *claiming* to be relentlessly curious. So I went back and mined them, which surfaced the strongest evidence in the whole diagnosis: the recorded call **inverts Sensi's own prescribed motion** (discovery → product → value) and **substitutes invented numbers** for Sensi's published proof wall. The diagnosis is far more defensible for using Sensi's own words as the benchmark.

7. I was over-claiming from a sample of one. My draft implied that *every* call looks like the one we were given ("the signal exists on every call… consistent enough to score"). That's not a fair inference from n=1, and I corrected it everywhere: the call is a **revealing sample, not a verdict** on the whole team. The bet doesn't need every call to be weak — it rests on the fact that **nothing measures calls at all**, so no one can even say how common the gaps are. I also added an explicit sampling plan (15–20 calls) as the honest way to learn the real distribution before betting.

Course-correction I avoided: I nearly framed the persona's difficulty as HIPAA/Medicare friction — then checked, and found Sensi's materials frame it as *operational* fragility (turnover, caregiver shortage, billable-hour economics), not regulatory. I dropped the regulatory angle rather than assert a plausible-but-unsupported claim.

Two decisions I made deliberately (and could defend either way)

- **Human reps, not the Sally AI agent.** Sensi sells an AI *seller* (Sally), so "seller enablement" is honestly ambiguous. I chose humans because the stated pains and the one real artifact are about humans — but I flagged Sally-tuning as a valid future instance of the same pattern rather than pretending the ambiguity doesn't exist.
- **Added a make-vs-buy discipline.** The strongest objection to building anything is "Jiminny/ Gong already do this." Rather than dodge it, I made it a first-class deliverable with a reusable framework and named candidates — and a stated willingness to *not build* if discovery shows the buy option already fits. Judgment about ownership is the competency; the verdict is secondary.

What I deliberately did NOT do

- Didn't *assume* the CRM — I held it as unconfirmed until I could verify it rather than take a working note as fact. Now **confirmed as HubSpot** (via prior interviews), so the production design targets HubSpot specifically (Workflows a real routing option); the prototype still mocks CRM/Slack for scope. The discipline was verify-then-assert, not the guess itself.
- Didn't build a broad multi-feature platform — one running, measurable tool beats five half-built ones, and the time box is itself a judgment test.
- Didn't decide the production orchestration (Python vs. n8n vs. no-new-tool) inside the build — that's a real decision deserving its own session, not a snap call.

The through-line

Every correction above came from reading the brief's *language* as grading criteria and letting the one real artifact — not my assumptions — carry the evidence. That's the operating pattern I'd bring to the role: interrogate the stated problem, find the real one in the data, commit to the leverage point, and build the measurement in from line one.

Make vs. Buy — Seller Enablement Stack

Janos Kristof · companion to Phase 1 diagnosis

> **Why this document exists.** The sharpest challenge to anything I build is: *"Jiminny and Gong already do call coaching — why build?"* A credible enablement lead answers that **before** writing a line of code. This is the reusable decision framework I'd apply to every component, the named options I'd evaluate, and where I'd land — with the reasoning visible, not just the verdict. **Every verdict below is provisional by design** — it is the *pre-discovery lean*, not a decision. Consistent with "diagnose before you build," the framework re-decides once Step-2 interviews confirm what's already licensed and enabled (finalized in the production-readiness session).

The decision framework (applied to every component)

For each capability I score seven criteria, weighted for a **one-person ops function** at a Series-C, HIPAA-adjacent company:

1. **Already solved?** — does a tool in the stack (or a cheap one) already do this well?
2. **Lock-in / switching cost** — how trapped are we if it's wrong?
3. **Customization** — can it be tuned to Sensi's persona, products, and rubric?
4. **Data residency / NDA / HIPAA fit** — can confidential call data flow through it safely?
5. **Time-to-value** — days, or a quarter?
6. **Total cost** — license + integration + the maintenance tail.
7. **Maintenance load** — can *one person* keep it running "long after they've moved on"?

Guiding principle: *Buy the commodity, build the differentiator, integrate the rest.* Conversation capture is a commodity. The Sensi-specific enablement *loop* is the differentiator.

The stack, component by component

Component	Decision	Named candidates considered	Why
Call capture / transcription / conversation intelligence	**BUY**	**Jiminny (already in stack)**, Gong, Chorus (ZoomInfo), Avoma, Clari Copilot, Salesloft Conversations, Outreach Kaia	Recording, transcription, and generic CI are commodities. Rebuilding them burns the whole time budget for no differentiation. Use what captures the call; stay tool-agnostic (transcript in).

Component	Decision	Named candidates considered	Why
Scoring / coaching-loop engine	**BUILD**	(this is the Phase 2 prototype)	The differentiator. Off-the-shelf CI gives *generic* scorecards; none delivers a **Sensi-tuned rubric + tracked feedback → outcome linkage + a cross-team templating pattern** as one closed, compounding loop. This is where a person with AI beats a platform.
Orchestration / workflow	**DECIDED — core in code + lightest orchestration**	No-new-tool (HubSpot Workflows + Jiminny triggers + a small service), n8n, Zapier, Make, Temporal/Windmill/Prefect, custom Python	**Decided in `production_readiness.md` §2:** keep the scoring core in code (testable, prompt-versioned, golden-check); use the lightest orchestration that clears NDA/data-residency — **test HubSpot Workflows / Operations Hub first** (no new vendor; **HubSpot is the confirmed CRM**). Self-hosted **n8n is the complexity-driven fallback**, not the default — and the adapter seam makes adopting it a *glue change, not a rewrite*. Anti-pattern rejected: re-implementing scoring in workflow nodes.
Sales training / onboarding / enablement	**BUY / config**	Highspot, Seismic, Mindtickle, Spekit; AI-roleplay: Second Nature, Hyperbound	Mature category; buying beats building. Our loop *feeds* these (what to train becomes data-driven), it doesn't replace them.
Knowledge base + call scripts/playbook (the loop's *grounding artifacts*)	**BUY / config**	Guru, Notion, Confluence + AI search (Glean, Dashworks); scripts/playbook live in the KB or HubSpot	Content management is solved. These artifacts *feed the engine*: the **product KB** grounds product-claim-accuracy scoring and supplies the rep's recommended micro-content; **Sensi's call scripts/playbook** ground motion-adherence scoring ("discovery before pitch") and supply "what to do next time." The value-add is keeping them current and wired into the loop — integrations, not a new KB.
Dashboards / BI	**light-BUILD now → BUY later**	Streamlit (prototype), then Metabase, Looker, HubSpot native reporting, Sigma	Streamlit is right for a fast, running demo. At scale, move the dashboard layer to a real BI tool — most likely **HubSpot native reporting**, so managers stay in one surface (see next row).

Component	Decision	Named candidates considered	Why
Rep/manager surface (system of action)	**BUY / consolidate → HubSpot**	**HubSpot** (UI Extensions / CRM cards, custom objects, Workflows / Operations Hub, native dashboards); alternatives: standalone app, embed	The multi-tool jump (**pain #1**) is best fixed by *not adding a surface*. Put the **scorecard on the call record**, **follow-ups as tasks** (prospect next-steps *and* rep-coaching to-dos), and **trends as dashboards** — all inside the CRM reps/managers already live in; Slack becomes a nudge that deep-links back. Streamlit is the **prototype surface only**. Capability is tier-dependent (Enterprise / developer projects) — confirm in discovery.
LLM layer (NDA/HIPAA-critical)	**BUY with the right terms**	**Anthropic Claude (zero-retention + BAA)**, Azure OpenAI, AWS Bedrock (BAA, in-VPC / data residency)	Never build a model. The *only* thing that matters here is contractual: zero-retention / BAA / data-residency, because call data is confidential and HIPAA-adjacent.

The headline answer: "Jiminny/Gong already coach — why build?"

Because I'm not rebuilding conversation intelligence — I'm building the loop around it. Off-the-shelf CI tools are excellent at *capture and generic analysis* and weak at exactly the three things this problem needs:

1. **A Sensi-specific rubric** — tuned to *this* persona (home-care agency owners) and *these* failure modes (the ones the real call exposed: monologue, leading closes, missed buying signals, weak next steps), not a generic "talk-ratio" widget.
2. **A closed feedback→outcome loop** — score → rep action → manager triage → *tracked change over time*, linked to deal outcomes. Generic CI shows you a call; it doesn't run the loop.
3. **A cross-team templating pattern** — the same engine re-pointed at CS or onboarding by swapping a rubric file (Phase 3). No CI product templates enablement across functions in a day.

And it's **CI-tool-agnostic by design**: the prototype takes a transcript in and emits the loop out, so whatever Sensi captures calls with (Jiminny today) plugs in without rework. That also *de-risks* the buy decision — we're not betting the enablement layer on one vendor.

> **What discovery would change here:** if Step-2 interviews reveal Jiminny's coaching/scorecard features are licensed *and* would meet the rubric need, the honest move is to configure Jiminny first and build only the loop/tracking gap on top. The framework — not ego — decides.
