Phase 1 — Diagnose Before You Build

Seller Enablement Intelligence

Janos Kristof · GTM AI Enablement · *prepared under NDA, call data anonymized*

The stated problem is six pains. The real problem is one.

The brief lists six pains. Treated as a checklist, they invite six half-built fixes. Read as **symptoms**, they share a single root cause:

> **There is no closed loop that turns each sales call into tracked, improving rep behavior.**

Sensi generates rich behavioral signal on every call — and throws it away. That measurement vacuum *is* the problem. Fixing it is the leverage point.

I mined every source — then pressure-tested one call

I worked the brief, the GTM deck, the Guide Book, the product/customer materials — and the one real sales call. That call is **a sample, not a verdict**: it shows the *kind* of gap that goes uncaught, not that every call looks like this. Anonymized, it shows:

- Rep speaks **~85–90%** of the call — monologue, not discovery
- A **leading close**: *"Would you agree I'm being conservative?"* → *"Yes, because I have nothing to disagree."* — compliance, not conviction
- The **biggest fact surfaces by accident at minute 47**: the prospect is *selling his business*
- **No firm next step** booked; manufactured "offer expires this month" urgency

Today nothing scores any call — so no one knows how common these gaps are. That vacuum is the problem.

The tell: this call broke Sensi's *own* playbook

Not just weak in the abstract — it departs from Sensi's **own** deck. A scoring loop would catch this automatically; today nothing does.

- **Motion inverted** — Sensi's deck prescribes *discovery → product → customer story & value*. The rep opened with a screen-share, skipped discovery, ran a DIY ROI calculator.
- **Invented numbers instead of Sensi's published proof:**

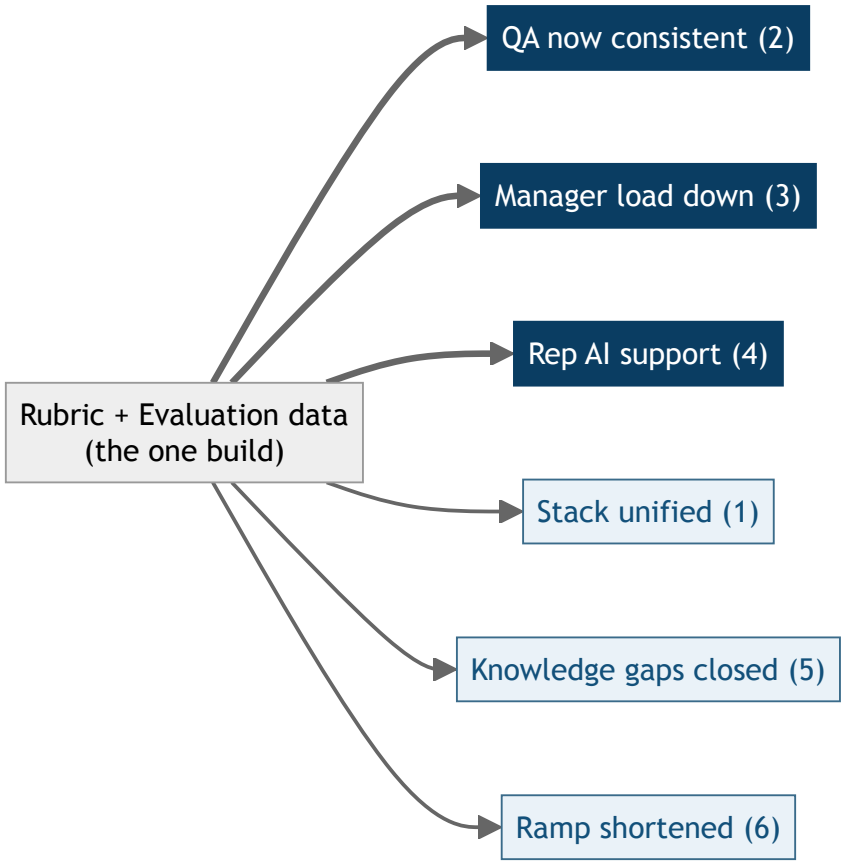

Rep said (this call)	Sensi actually publishes
"$623K, unbelievably conservative"	~$500K avg savings — the rep *overshoots* the official figure
"3.3 months LoS, 1,000-agency survey"	"2× length of stay"; no such survey exists
"Sally = 3–4× a salesperson"	"your entire inside sales force in one agent"

The point isn't that every rep does this — it's that nothing measures whether *any* call uses Sensi's own motion and proof.

Before building, I'd confirm — not assume

- **Interview map, in order:** Ops leadership → VP Sales → 3 reps (top / ramping / struggling) → 1–2 managers → RevOps/HubSpot owner → onboarding → product marketing
- **Sample, don't assume:** score **15–20 recent calls across 3 rep tiers** — I would *not* treat one call as representative
- **Data I'd pull:** win/loss by rep & stage, ramp cohorts, existing Jiminny analytics, call coverage, stage-conversion leaks
- **Verified, not assumed:** CRM = **HubSpot** (confirmed) — a real integration + a no-new-tool routing option

One build moves the most pains

Thick arrows = directly solved · **thin arrows** = unlocked. Same two artifacts power all six.

The bet I'm taking into Phase 2

> **Biggest leverage point: an automated post-call evaluation + coaching loop.**

Why I believe it

- The gap is real *and invisible* — nothing measures it, so the loop turns an unknown into a managed number
- It's the **cheapest place to install measurement** — it *creates* the baseline from call one
- It attacks the binding constraint — **manager capacity**
- It **compounds**: the same loop later templates onto onboarding, CS, any team

What I'd build to test it → the *Rep Coach* scorecard (Phase 2).

Falsifiable — I'd rather be wrong in week 2 than month 6

- Reps don't return to it → feedback isn't actionable enough
- Scores don't move behavior in ~3–4 weeks → the rubric measures the wrong things
- Managers don't trust the scores → evidence/explainability too thin

Each has a leading metric in the Phase 2 tool. **Next: build the thing that runs.**
